# AN APPROXIMATE SOLUTION OF THE MASTER EQUATION WITH THE DISSIPATOR BEING <br> A SET OF PROJECTORS 

By<br>Kazuyuki Fujii<br>(Received November 12, 2007; Revised January 11, 2008)

#### Abstract

In this paper we consider a quantum open system and treat the master equation with some restricted dissipator which consists of a set of projection operators (projectors). The exact solution is given under the commutable approximation (in our terminology). This is the first step for constructing the general solution.

Quantum Computation (Computer) is one of main subjects in Quantum Physics. To realize it we must overcome severe problems arising from Decoherence, so we need to study Quantum Open System to control decoherence (if possible).

In this paper we revisit dynamics of a quantum open system as a test case. See [1] as a general introduction to this subject. First we explain the purpose and strategy within our necessity.

We consider a quantum open system $S$ coupled to the environment $E$. Then the total system $S+E$ is described by the Hamiltonian

$$
H_{S+E}=H_{S} \otimes \mathbf{1}_{E}+\mathbf{1}_{S} \otimes H_{E}+H_{I}
$$

where $H_{S}, H_{E}$ are respectively the Hamiltonians of the system and environment, and $H_{I}$ is the Hamiltonian of the interaction.
Then under several assumptions (see [1]) the reduced dynamics of the system (which is not unitary) is given by the Master Equation

$$
\begin{equation*}
\frac{\partial}{\partial t} \rho=-i\left[H_{S}, \rho\right]-\mathcal{D}(\rho) \tag{1}
\end{equation*}
$$

with the dissipator being the usual Lindblad form

$$
\begin{equation*}
\mathcal{D}(\rho)=\frac{1}{2} \sum_{\{j\}}\left(A_{j}^{\dagger} A_{j} \rho+\rho A_{j}^{\dagger} A_{j}-2 A_{j} \rho A_{j}^{\dagger}\right) . \tag{2}
\end{equation*}
$$

2000 Mathematics Subject Classification:
Key words and phrases:

Here $\rho \equiv \rho(t)$ is the density operator (matrix) of the system.
It is not easy to solve the equation (1) with the dissipator (2), so we make a simple and convenient assumption. Namely, the generators $\left\{A_{j}\right\}$ are given by $A_{j}=\sqrt{\lambda_{j}} P_{j}$ with projectors $\left\{P_{j}\right\} ; P_{j}^{\dagger}=P_{j}, P_{j}^{2}=P_{j}, P_{j} P_{k}=\delta_{j k} P_{k}$. Note that we don't assume the rank $P_{j}=1$ (extended models). Then the dissipator becomes

$$
\begin{equation*}
\mathcal{D}(\rho)=\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \rho+\rho P_{j}-2 P_{j} \rho P_{j}\right) \tag{3}
\end{equation*}
$$

where $\left\{\lambda_{j}\right\}$ are decoherence parameters to determine the strength of the interaction. See [2], [3] (in [3] there is a very compact description on this subject). It is interesting to rewrite (3) as

$$
\begin{equation*}
\mathcal{D}(\rho)=\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left\{P_{j} \rho\left(\mathbf{1}-P_{j}\right)+\left(\mathbf{1}-P_{j}\right) \rho P_{j}\right\} \equiv \frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \rho Q_{j}+Q_{j} \rho P_{j}\right) . \tag{4}
\end{equation*}
$$

Note that $\left\{Q_{j}\right\}$ are also projectors satisfying $P_{j} Q_{j}=Q_{j} P_{j}=0$ for $j \in\{j\}$.
As a result we have only to solve the equation

$$
\begin{equation*}
\frac{\partial}{\partial t} \rho=-i(H \rho-\rho H)-\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \rho Q_{j}+Q_{j} \rho P_{j}\right) \tag{5}
\end{equation*}
$$

where we have set $H=H_{S}$ for simplicity.
In order to study the equation (5) let us make some mathematical preliminaries. For a matrix $X=\left(x_{i j}\right) \in M(n ; \mathbf{C})$ we correspond to the vector $\widehat{X} \in \mathbf{C}^{n^{2}}$ as

$$
\begin{equation*}
X=\left(x_{i j}\right) \longrightarrow \widehat{X}=\left(x_{11}, x_{12}, \cdots, x_{1 n}, \cdots \cdots, x_{n 1}, x_{n 2}, \cdots, x_{n n}\right)^{T} \tag{6}
\end{equation*}
$$

where $T$ means the transpose. Then the following formula is well-known

$$
\begin{equation*}
\widehat{A X B}=\left(A \otimes B^{T}\right) \widehat{X} \tag{7}
\end{equation*}
$$

for $A, B, X \in M(n ; \mathbf{C})$. Since the proof is easy we leave it to readers.
By use of the formula the equation (5) can be rewritten as

$$
\begin{equation*}
\frac{\partial}{\partial t} \widehat{\rho}=\left\{-i\left(H \otimes \mathbf{1}-\mathbf{1} \otimes H^{T}\right)-\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \widehat{\rho} \tag{8}
\end{equation*}
$$

therefore the formal solution is given by

$$
\begin{equation*}
\widehat{\rho}(t)=\exp \left\{-i t\left(H \otimes \mathbf{1}-\mathbf{1} \otimes H^{T}\right)-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \widehat{\rho}(0) \tag{9}
\end{equation*}
$$

To calculate $\exp (\cdots)$ explicitly is almost impossible, so we must appeal to some approximation method. For that let us remind the Baker-CampbellHausdorff (B-C-H) formula. For $A, B \in M(n ; \mathbf{C})$ we want to decompose as

$$
\begin{equation*}
\mathrm{e}^{A+B}=\mathrm{e}^{A} \mathrm{e}^{I(A, B)} \mathrm{e}^{B} \tag{10}
\end{equation*}
$$

The "interaction" term $I(A, B)$ is given by

$$
\begin{equation*}
I(A, B)=-\frac{1}{2}[A, B]+\frac{1}{6}\{[[A, B], B]+[A,[A, B]]\}+\cdots \tag{11}
\end{equation*}
$$

The proof is easy. In fact, $\mathrm{e}^{I(A, B)}=\mathrm{e}^{-A} \mathrm{e}^{A+B} \mathrm{e}^{-B}$ by (10) and we have only to apply the B-C-H formula ([4] and see also [5] as an interesting topic)

$$
\mathrm{e}^{X} \mathrm{e}^{Y}=\mathrm{e}^{X+Y+(1 / 2)[X, Y]+(1 / 12)\{[[X, Y], Y]+[X,[X, Y]]\}+\cdots} \quad \text { for } X, Y \in M(n ; \mathbf{C})
$$

two times.
For

$$
A=-i t\left(H \otimes \mathbf{1}-\mathbf{1} \otimes H^{T}\right), \quad B=-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)
$$

there is no method to calculate $\mathrm{e}^{I(A, B)}$ explicitly as far as we know. Therefore we ignore this term, namely let us call it the "commutable approximation" ${ }^{1}$.

Under the commutable approximation we have only to calculate

$$
\begin{align*}
\widehat{\rho}(t) & \approx \exp \left\{-i t\left(H \otimes \mathbf{1}-\mathbf{1} \otimes H^{T}\right)\right\} \exp \left\{-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \widehat{\rho}(0) \\
& =\left(\mathrm{e}^{-i t H} \otimes \mathrm{e}^{i t H^{T}}\right) \exp \left\{-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \widehat{\rho}(0) \\
& =\left(\mathrm{e}^{-i t H} \otimes\left(\mathrm{e}^{i t H}\right)^{T}\right) \exp \left\{-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \widehat{\rho}(0) . \tag{12}
\end{align*}
$$

[^0]Next let us calculate the second term in (12), which is not so difficult as follows.

$$
\begin{align*}
(\sharp) & \equiv \exp \left\{-t \sum_{\{j\}}\left(\lambda_{j} / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \\
& =\prod_{\{j\}} \exp \left\{\left(-\lambda_{j} t / 2\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \\
& =\prod_{\{j\}}\left\{\mathbf{1} \otimes \mathbf{1}+\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)\right\} \tag{13}
\end{align*}
$$

where we have used facts
(a) $\left\{P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T} \mid j \in\{j\}\right\}$ are projectors commuting with each other.
(b) $\mathrm{e}^{\lambda R}=\mathbf{1}+\left(\mathrm{e}^{\lambda}-1\right) R$ if $R$ is a projector.

Here we set $R_{j}=P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}$. For $i<j<k$ it is easy to see
(c) $R_{i} R_{j}=\left(P_{i} \otimes Q_{i}^{T}+Q_{i} \otimes P_{i}^{T}\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)=P_{i} \otimes P_{j}^{T}+P_{j} \otimes P_{i}^{T}$.
(d) $R_{i} R_{j} R_{k}=\left(P_{i} \otimes P_{j}^{T}+P_{j} \otimes P_{i}^{T}\right)\left(P_{k} \otimes Q_{k}^{T}+Q_{k} \otimes P_{k}^{T}\right)=0$.

From (13) and (c), (d)

$$
\begin{align*}
(\sharp)= & \prod_{\{j\}}\left\{\mathbf{1} \otimes \mathbf{1}+\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right) R_{j}\right\} \\
= & \mathbf{1} \otimes \mathbf{1}+\sum_{j}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right) R_{j}+\sum_{j<k}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(\mathrm{e}^{-\lambda_{k} t / 2}-1\right) R_{j} R_{k} \\
= & \mathbf{1} \otimes \mathbf{1}+\sum_{j}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)+ \\
& \sum_{j<k}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(\mathrm{e}^{-\lambda_{k} t / 2}-1\right)\left(P_{j} \otimes P_{k}^{T}+P_{k} \otimes P_{j}^{T}\right) \tag{14}
\end{align*}
$$

Therefore

$$
\begin{align*}
\widehat{\rho}(t) \approx & \left(\mathrm{e}^{-i t H} \otimes\left(\mathrm{e}^{i t H}\right)^{T}\right)\left\{\mathbf{1} \otimes \mathbf{1}+\sum_{j}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(P_{j} \otimes Q_{j}^{T}+Q_{j} \otimes P_{j}^{T}\right)+\right. \\
& \left.\sum_{j<k}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(\mathrm{e}^{-\lambda_{k} t / 2}-1\right)\left(P_{j} \otimes P_{k}^{T}+P_{k} \otimes P_{j}^{T}\right)\right\} \widehat{\rho}(0) \tag{15}
\end{align*}
$$

By restoring to matrix form by use of (7) we finally obtain

$$
\begin{align*}
\rho(t) & \approx \mathrm{e}^{-i t H}\left\{\rho(0)+\sum_{j}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(P_{j} \rho(0) Q_{j}+Q_{j} \rho(0) P_{j}\right)+\right. \\
& \left.\sum_{j<k}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(\mathrm{e}^{-\lambda_{k} t / 2}-1\right)\left(P_{j} \rho(0) P_{k}+P_{k} \rho(0) P_{j}\right)\right\} \mathrm{e}^{i t H} \tag{16}
\end{align*}
$$

or

$$
\begin{align*}
& \rho(t) \approx \mathrm{e}^{-i t H}\left\{\rho(0)+\sum_{j}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(P_{j} \rho(0) Q_{j}+Q_{j} \rho(0) P_{j}\right)+\right. \\
& \left.\frac{1}{2} \sum_{j \neq k}\left(\mathrm{e}^{-\lambda_{j} t / 2}-1\right)\left(\mathrm{e}^{-\lambda_{k} t / 2}-1\right)\left(P_{j} \rho(0) P_{k}+P_{k} \rho(0) P_{j}\right)\right\} \mathrm{e}^{i t H} \tag{17}
\end{align*}
$$

for $j, k \in\{j\}$. This is the main result.
A comment is in order. In [2] and [3] the master equation like (5) in the two qubit system is treated. A general density matrix in the case is written as

$$
\rho(t)=\frac{1}{4}\left(\mathbf{1}_{2} \otimes \mathbf{1}_{2}+p_{i}(t) \sigma_{i} \otimes \mathbf{1}_{2}+q_{j}(t) \mathbf{1}_{2} \otimes \sigma_{j}+r_{i j}(t) \sigma_{i} \otimes \sigma_{j}\right), \quad 1 \leq i, j \leq 3
$$

where the usual Einstein's notation on summation is used. Using this expression one can study the equation coming from pure decoherence term

$$
\frac{\partial}{\partial t} \rho=-\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \rho+\rho P_{j}-2 P_{j} \rho P_{j}\right)=-\frac{1}{2} \sum_{\{j\}} \lambda_{j}\left(P_{j} \rho Q_{j}+Q_{j} \rho P_{j}\right)
$$

The equation is then reduced to a set of (relatively simple) equations of $\{p\}$, $\{q\}$ and $\{r\}$ and one can solve them. However, such a (restricted) method is irrelevant as shown in the paper. Our method is quite general!

In this paper we considered the master equation with the dissipative being a set of projectors and constructed the exact solution under the commutable approximation. This is just the first step for constructing the general solution for the equation.

In order to take one step forward we must take the "interaction" term $I(A, B)$ in (11) into consideration. However, such a method to calculate it has not been known as far as we know. Therefore it may be reasonable to restrict our target to some simple models. Further work will be needed and we will report it in the near future, [6].

On the other hand we are studying some related topics, see [7] and [8]. However, we make no comment on them in the paper.

Lastly, we conclude the paper by stating our motivation. We are studying a model of quantum computation (computer) based on Cavity QED (see [9] and [10]), so to construct a more realistic model of (robust) quantum computer we have to study severe problems arising from decoherence. This is our future task.
